

## INTRODUCTION

The objective of the CMPE 415 Homework #4 was to introduce the concept of creating and implementing SSRAM memory blocks and FIFO, dual port memory blocks. My entire project is completely functional. Homework #4 part 1, regarding the three SSRAM memory blocks and multiplication, is all stored inside the folder titled “**multiplication\_hw4**”. My own memory block generation code can be tested if **top\_multiplication** is implemented as the top module and then the test bench named **pt1\_tb** is run. My IPCORE memory block generation code can be tested if **top\_multiplication\_IPCORE** is implemented as the top module and the test bench named **pt1\_tb2** is run. Homework #4 part 2, regarding the first-in-first-out (FIFO) dual-port memory block, is stored inside the folder titled “**fifo\_hw4**”. My own FIFO memory block generation code can be tested if **fifo\_block** is implemented as the top module, and the test bench named **pt2\_tb** is run. My IPCORE FIFO memory block generation code, which is implemented inside “**top\_fifo\_block**”, can be tested if the test bench named **pt2\_tb2** is run. In this document I will describe my code development process, the finite state machines involved with each part of the homework and my results.

## MULTIPLE MEMORY BLOCKS AND MULTIPLICATION

To approach this problem, I had to think about how to design the system, and a block diagram, shown in figure 1, expresses the basic design and functionality of different components of the memory handling.

**Figure 1: Memory Accessing & Multiplication Block Diagram**

Once the block diagram was created, I had to consider how to control the components so that they will read data from two memory blocks, multiply the data, then write that obtained data into another memory block. Below are the following steps that I used for controlling the sequence:

1. Remain idle until a go signal is received
2. Get data from SSRAM\_a[i] and SSRAM\_b[i] (repeat until last address)
3. Make sure data is obtained from SSRAM\_a[127] and SSRAM\_b[127] (last address)
4.  $SSRAM\_p[i] = SSRAM\_a[i] \times SSRAM\_b[i]$
5. Set done signal high to signify that all multiplication operations are complete

Once I knew that these steps had to be complete for a successful 128-depth multiplication operation, a control signal table, shown in table 1, was created so that I knew what signals are required for each step to occur.

**Table 1: Signal Control**

STEP	NAME	GO	DONE	RD_AB	WR_P	CLK_AB	CLK_P
1	Idle	1/0	0	0	0	0	0
2	Get A & B Values	0	0	1	0	1	1
3	Get Last A & B Values	0	0	1	0	0	1
4	Multiply & Store	0	0	1	1	0	0
5	Finish	0	1	0	0	0	0

All of the signals listed in table 1 are the enable signals involved in the system. Now that I knew what components I had at my disposal, the steps required, the signals required to perform the steps, all that is left to understand is when to perform each of the steps. A transition function

table was created, shown in table 2, to organize how each of the states will interface with eachother.

### **Table 2: State Transitioning**

CURRENT STATE	INPUT READY	NEXT STATE
1	go = 0	0
1	go = 1	2
2	X	4
3	X	2
4	mid_vector = 1	2
4	before_last_address = 1	3
4	last_address = 1	5
5	X	1

\*\* NOTE: Xs are “don’t care” conditions

Now that all the logic has been prepared, I designed my system.

The outputs obtained when testing can be seen in the figures below, however the text outputs of the test bench will be shown in Appendix A, which is at the end of the document, due to its length.

**Figure 2: Output of the Signal Timing Diagram Obtained from Test Bench for Pt1 step iii**

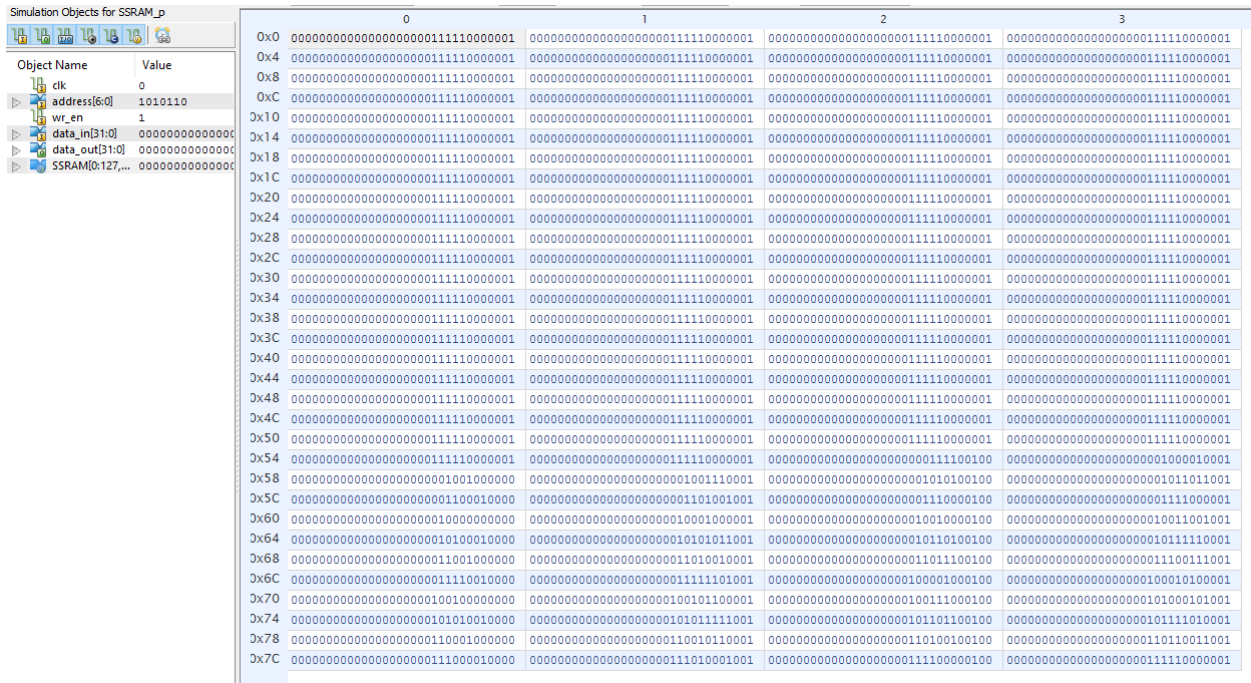

The timing diagram above shows that go is high for a moment and the program runs, then a done signal is set high around the 600ns, then everything has reset and is waiting for another go signal.

					0x7C 0000000000000000	0000000000000001	0000000000000010	0000000000000011

**Figure 3: SSRAM\_a Memory Stored**

[illegible]

**Figure 4: SSRAM b Memory Stored**

**Figure 5: SSRAM\_p Memory Stored**

These memory blocks show that since the data stored in `SSRAM_a` and `SSRAM_b` are identical, the data stored in `SSRAM_p`, after running the 128-depth multiplication system, is stored with square values, which are expected.

The output obtained from the generated IPCORE memory blocks is shown below:

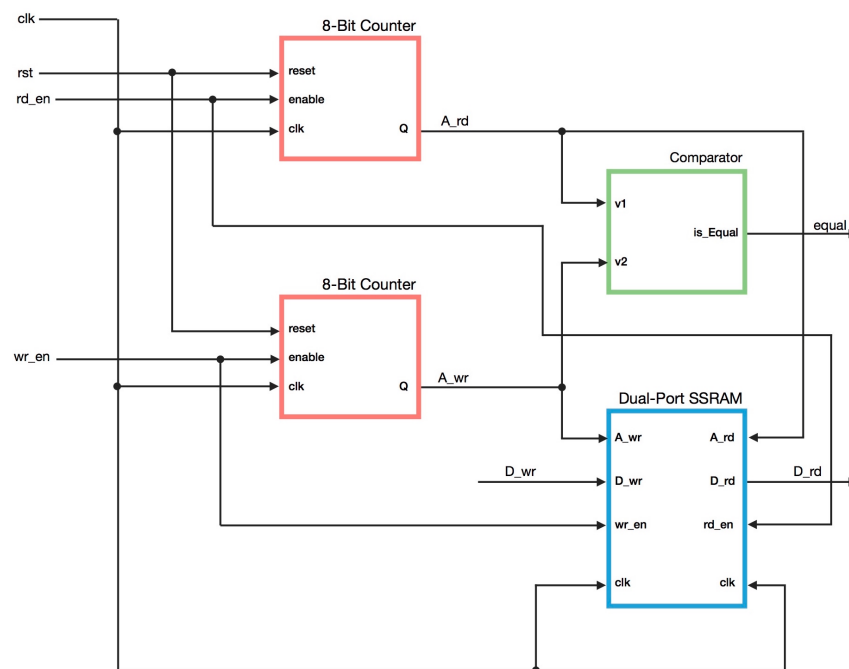

**Figure 6: IPCORE Signal Timing Diagram for Pt1 step iv**

The only real difference is that the IP CORE initialized the output from the SSRAM\_p memory block. Since the memory is not accessible, the information is shown in the form of test bench output monitoring in Appendix B.

## DUAL-PORT FIFO MEMORY BLOCK HANDLING

To approach this problem, I had to think about how to design the system, and a block diagram, shown in figure 7, expresses the basic design and functionality of different components of the FIFO memory handling.

**Figure 7: FIFO Memory Block with Dual-Port SSRAM**

Handling the system, there was a basic procedure followed:

### Read:

1. Read enable signal is high
2. Read Counter increments
3. Check if the read address is the same as the write address
  - a. If they are the same, and the last successful operation was a read, the FIFO memory is empty (go to step 4)
  - b. If they are different, the FIFO memory has good data (go to step 5)
4. Do not read
5. Read the data and output it

### Write:

1. Write enable signal is high
2. Write Counter increments
3. Check if the read address is the same as the write address
  - a. If they are the same, and the last successful operation was a write, the FIFO memory is full (go to step 4)
  - b. If they are different, the FIFO memory has free space (go to step 5)
4. Do not write
5. Write the data and output it

The test I ran on my FIFO memory block and the IPCORE generated FIFO memory block is that I ran the write signal 260 times, which exceeds the depth size of 256, so the full signal should be high for some duration. Then I ran the read signal high 260 times, so it should read out the first 256 stored values and then the empty signal should be high for some duration. Then I write 10 more items into the FIFO so that in the end, both full and empty should be low.

The outputs obtained when running my own FIFO memory block and then the IPCORE generated FIFO memory block are shown in figures 8 and 9 below and in Appendix C and Appendix D, respectively:

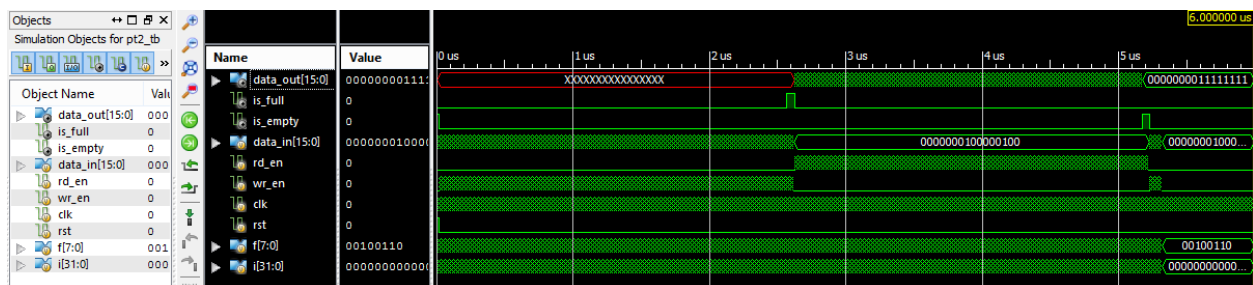

Figure 8: Signal Timing Diagram Obtained from Pt2 step iii

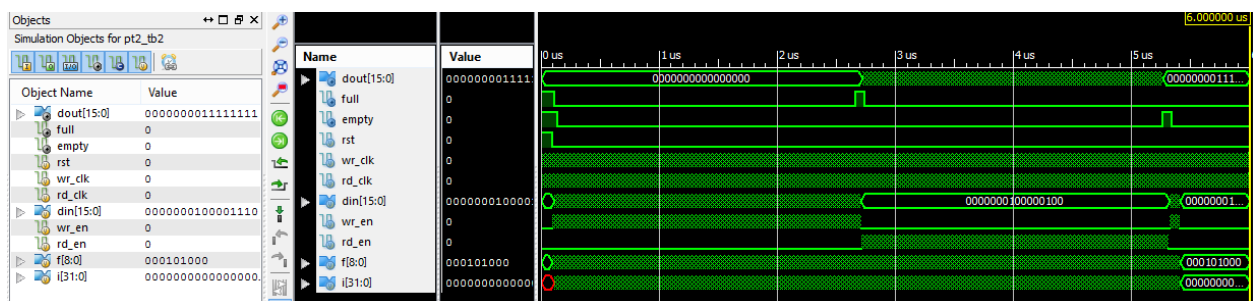

Figure 9: Signal Timing Diagram Obtained from Pt2 step iv

The only difference between figure 8 and figure 9 is that the IPCORE FIFO block initializes data\_out to 0s, while I do not.

## **CONCLUSION**

From completing this project, I learned about how to design, create and implement memory into a full system with controls and computations in Verilog. I also learned how to utilize the memory generator to create the memories I had just created, so that in the future, I know how to quickly generate different types of memory blocks. One key beneficial skill I learned during the project is how to debug memory. I figured out how to view what is stored in memory and how to make an effective test bench table output, shown in the various Appendixes below.
